
Lab5- Socket programming

TCP Server-Client implementation with multiple clients in C

Socket programming is a way of connecting two nodes on a network to communicate with each other. One socket(node) listens on a particular port at an IP, while another socket reaches out to the other to form a connection. The server forms the listener socket while the client reaches out to the server. TCP/IP provides end-to-end connectivity specifying how data should be formatted, addressed, transmitted, routed, and received at the destination can be used on the internet, and in stand-alone private networks, it is organized into layers.

In this practical, we learned about handling multiple connection requests from clients and also handling the communication requests made by clients and responding to them in accordance with our logic. For the sake of simplicity, in this implementation, we have taken a message as input from the client, displayed it on the server-side, and taken another user input at server-side and sent it back to the client, basically like a chatbot.

The screenshot shows a Linux desktop environment with four terminal windows open. The top-left window shows the server's log of connections and messages. The top-right window shows a client's interaction with the server. The bottom-left window shows another client's interaction. The bottom-right window shows a third client's interaction. The desktop has a dark theme and a dock with various application icons at the bottom.

harsh@harshs:~/Downloads$ ./client
Connected successfully
Send: Hello from client 3
Received: Hello client 3

Send: 

```

Conclusion

Through this practical application, we learned about TCP and implemented a basic communication setup between multiple clients and a server like a chatbot.
